| <p>How are living things classified?</p> <p>How are kingdoms determined?</p> | <p>Aristotle (384-322 BC) placed all organisms into 2 groups:</p> <ul style="list-style-type: none"> • animals: based on presence of “red blood,” the animal’s environment, & the size and shape of the animal • plants: according to structure and size of the plant & whether the plant was a tree, shrub, or herb (19) <p>Carolus Linnaeus (1700s)</p> <ul style="list-style-type: none"> • classified organisms based on similar structures • placed all organisms into 2 groups, called kingdoms <p>Robert H. Whittaker (1969)</p> <ul style="list-style-type: none"> • proposed a 5-kingdom system for classifying organisms • kingdoms Monera, Protista, Plantae, Fungi, and Animalia (20) |
| <p><i>Determining Domains</i></p> <p>What evidence is used to classify living things into groups?</p> | <ul style="list-style-type: none"> • systematics: current classification method • uses all the evidence that is known about organisms to classify them • includes: organism’s cell type, habitat, way the organism obtains food and energy, structure and function of its features, and common ancestry of organisms • also includes: molecular analysis- the study of molecules such as DNA within organisms <p>using systematics, scientists identified 2 distinct groups in Kingdom Monera: Bacteria and Archaea</p> <ul style="list-style-type: none"> • led to the development of another level of classification called domains • all organisms are classified into 1 of the 3 domains, and then into 1 of the 5 kingdoms (20) |
| <p><i>Scientific Names</i></p> <p>What is binomial nomenclature?</p> | <ul style="list-style-type: none"> • the system we use for naming organisms • Linnaeus’s naming system • gives each organism a 2-word scientific name • the name of an organism’s species • species: a group of organisms that have similar traits and are able to produce fertile offspring • the first word is an organism’s genus • genus: a group of similar species • the second word might describe the organism’s appearance or behavior (21) |

| <p>How do species and genus relate to kingdoms and domains?</p> <p>Why does every species have a scientific name?</p> <p>Classification Tools</p> <ul style="list-style-type: none"> • What is a dichotomous key? • What is a cladogram? | <ul style="list-style-type: none"> • similar species are grouped into 1 genus • similar genera are grouped into families, orders, classes, phyla, kingdoms, and then domains (21) <p>common names might be used for a number of different species (i.e: bird, tree, mushroom) or organisms (i.e: pine trees), but an organism only has 1 scientific name</p> <ul style="list-style-type: none"> • each species has its own scientific name • scientific names are the same worldwide • communication about organisms more effective because everyone uses the same name for the same species (22) <ul style="list-style-type: none"> • a series of descriptions arranged in pairs that leads the user to the identification of an unknown organism • the chosen description leads to either another pair of statements or the identification of the organism • choices continue until the organism is identified (22) <ul style="list-style-type: none"> • a branched diagram that shows the relationships among organisms, including common ancestors • each branch follows a new characteristic • each characteristic is observed in all species to the right • i.e: salamander, lizard, hamster, chimpanzee have lungs, the salmon does not, therefore they are more closely related to each other than to the salmon (23) |
